Project Idea

PhishTrainer is an interactive training application that helps users identify phishing attacks through realistic simulated scenarios and instant feedback. Users analyze fake emails, decide whether they are legitimate or malicious, and receive detailed explanations highlighting the key warning signs. Fake login pages may be added as an optional second scenario type if time permits.

Target Users and Goals

The primary target users are students and non-technical users who want to improve their cybersecurity awareness. The main goal is to provide an engaging, self-paced learning experience that builds practical skills for recognizing phishing attempts in everyday digital life.

Core Features

- Dashboard showing training progress, score, and streak
- Scenario screen displaying simulated phishing emails (primary scenario type)
- Decision interface where users mark suspicious elements and give a verdict
- Feedback screen explaining red flags after each scenario
- History view listing completed scenarios and results
- Difficulty levels (easy, medium, hard)

Backend and API

No external backend is required. All scenario data will be stored as static JSON mock data within the frontend application. This allows the app to run entirely in the browser without any server-side infrastructure.

Project Scope

The application will consist of approximately five views with full React-based routing and state management. The focus lies on component-based architecture, responsive layout, and meaningful user interaction. Advanced features such as user authentication or a real backend API are explicitly out of scope for this course.

AI Tools

This document was drafted with the support of Claude (Anthropic). The tool was used to assist with wording and structure; all project-specific content and decisions were made and reviewed by the team.
